HE

Will need to explain what's in them. The main difference is that in the repeated measures, the same data structure is repeated across the columns with the subjects on the rows, and in the second, the repeated data is in single columns. The numerical data are counts, binary or scores.

For a first pass could we extract the following from the RP data:

Horse Session type
Session# Trial#
Latency Criterion (0/1)

Horse ID RPA
RPA1 1
45.01s 0
2
19.01s 1
3
36.01s 0

Session Summary: # trials criterion = 1
trials criterion =0
mean latency all trials
mean latency criterion =1
mean latency criterion=0
sum latency

For the RPA sessions only-
#sessions to reach criterion
sum trials to reach criterion

Will need to add a cohort code- 1 for Hillydale and 2 for CSU to all records.

Research questions
Is there a difference in latencies between sessions (**within** session types - RPA and RPH and **between** session types RPA vs RPH vs RPE etc)
Is the difference between criterion and non criterion trials significant
Is the difference between individual horses to acquire the RPA criterion- total trials and total sessions significant
Is the difference between individual horses to acquire the extinction criterion in RPE and RPER significant.
Cohort differences- is there a difference between performance at Hillydale vs CSU.

There will be more once I start seeing the early results but hopefully I will be able to get Rob's help for those.

I need to think more about the CB stuff, so will send that in a separate email.

Hoping you're having a good weekend.

Talk Tuesday

Cath
